Clark.

CONFIDENTIAL DATA ROOM

EXTREME NEURAL-NETWORK COMPRESSION

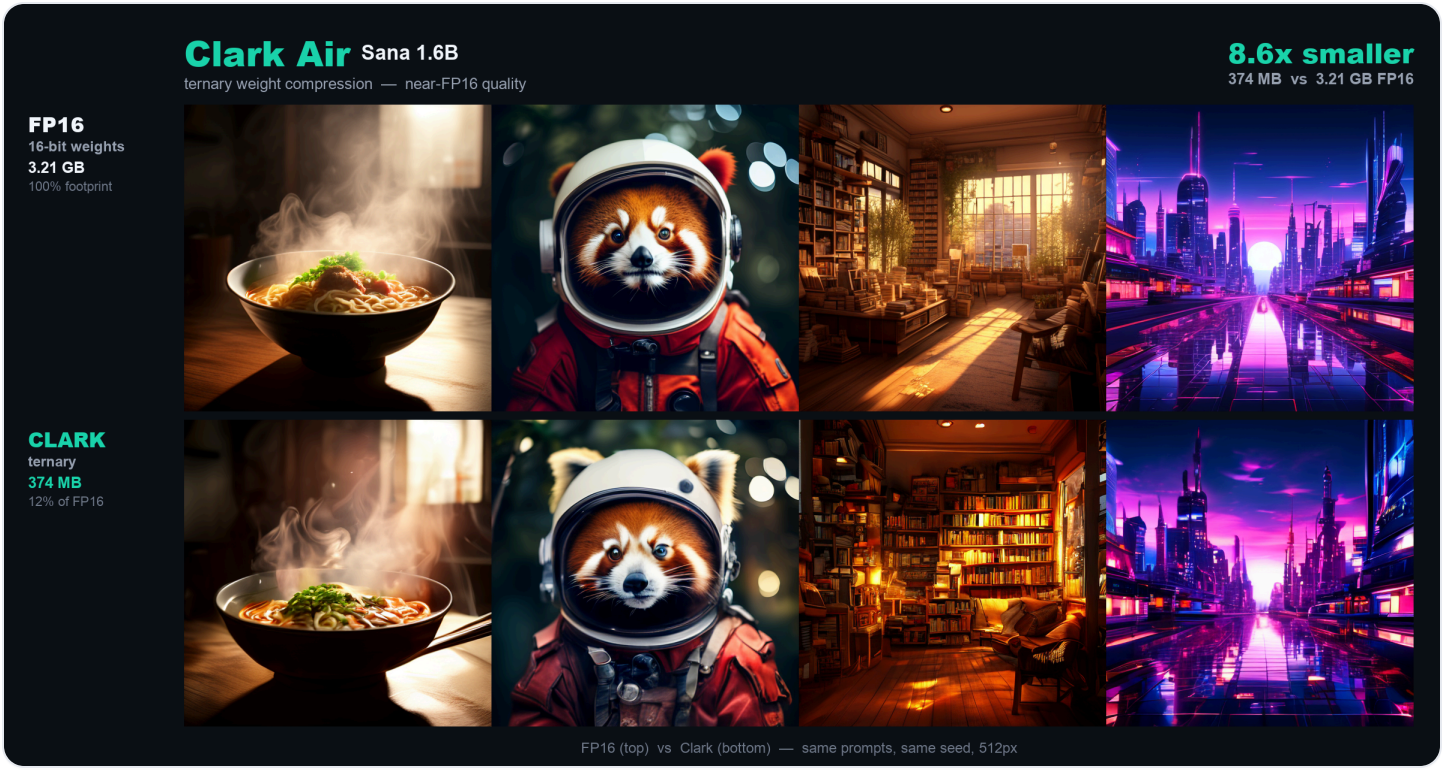

We make AI models 8.6× smaller with no visible quality loss — and the same method works on any transformer, including LLMs.

8.6×
smaller on disk vs. full precision (FP16)

12%
of original size — an 88% reduction

~FP16
quality retained — visually indistinguishable

AnyGPU
hardware-agnostic — no special silicon

Measured result. A 1.6B-parameter image model compressed from **3.21 GB → 374 MB**. Same prompts, same seed — output is visually identical.

ON-DISK FOOTPRINT — SANA 1.6B

Full precision (FP16) — 3.21 GB · 100%

Clark — 374 MB · 12%

8.6× smaller — the same model fits where **one-eighth** of it used to, so a single GPU serves **~8.6× more models** at **near-FP16 quality.**

Performance that holds up

8.6× smaller at near-FP16 quality, measured end-to-end on a real 1.6B model. Not a benchmark trick — the compressed model ships and runs.

Scales straight to LLMs

Clark compresses the **attention and projection weights that dominate every transformer.** LLM inference is the largest and fastest-growing cost in AI — Clark cuts the memory that drives it, putting bigger models on smaller, cheaper hardware.

One method, any model

Architecture- and hardware-agnostic. Proven on a diffusion transformer; the same approach generalizes to LLMs, vision, and multimodal models — no retraining of the customer's stack required.

WHY NOW

Memory is the bottleneck for serving AI. **8.6× smaller means ~8.6× cheaper memory, more models per GPU, and on-device deployment that was previously impossible** — across a market where every AI company pays the inference bill.
